BULLS FOR THE 21ST CENTURY

UNDERSTANDING FEED EFFICIENCY DATA – AN EXPLANATION OF

- ✓ RESIDUAL FEED INTAKE
- ✓ ADJUSTMENT TO FEED BILL
- ✓ EFFICIENCY EPDS

RFI = RESIDUAL FEED INTAKE

- RFI is the difference between actual intake and expected intake.
- Actual intake is measured at Snyder Livestock on *Growsafe®* equipment. We actually know how much each bull eats each day during the 70-day test.
- Animal scientists calculate expected intake for us. It is based upon average size, gain, and consumption for the entire test group.
- Negative numbers are good. A bull with a -3.5 RFI ate 3.5 pounds less each day than we expected – based upon his size and his rate of gain.

ADJUSTMENT TO FEED BILL IN 112 DAY TEST

- RFI numbers are used to calculate an adjustment to the feed bill.
- Adjustment = RFI x Ration Cost x 112 days.
- Example: -3.5 RFI x \$210 per ton x 112 days = -\$41.16
- This means that in 112 days, this bull *did not eat* \$41.16 worth of feed.

EFFICIENCY EPDS

Efficiency EPDs are now available. Negative RFI EPDs predict offspring with lower intake at a given performance level.
